Dependently Typed Programming: an Agda introduction

Conor McBride

February 21, 2011

Chapter 1

Vectors and Finite Sets

```
\begin{array}{lll} \textbf{data List } (X:\mathsf{Set}): \mathsf{Set \ where} \\ & \langle \rangle : & \mathsf{List \ } X \\ & \neg, \neg : X \to \mathsf{List \ } X \to \mathsf{List \ } X \\ \\ \mathsf{zap}: \left\{S \ T: \ \mathsf{Set}\right\} \to \mathsf{List \ } (S \to T) \to \mathsf{List \ } S \to \mathsf{List \ } T \\ \\ \mathsf{zap \ } \langle \rangle & \langle \rangle & = \langle \rangle \\ \\ \mathsf{zap \ } \langle f,fs \rangle \ (s,ss) & = f \ s,\mathsf{zap \ } fs \ ss \\ \\ \mathsf{zap \ } & - & = \langle \rangle & -\text{a \ dummy \ value, for \ cases \ we \ should \ not \ reach} \\ \end{array}
```

Agda has a very simple lexer and very few special characters. To a first approximation, (){}; stand alone and everything else must be delimited with whitespace.

That's the usual 'garbage in? garbage out!' deal. Logically, we might want to ensure the inverse: if we supply meaningful input, we want meaningful output. But what is meaningful input? Lists the same length! Locally, we have a *relative* notion of meaningfulness. What is meaningful output? We could say that if the inputs were the same length, we expect output of that length. How shall we express this property?

```
data Nat : Set where

zero : Nat
suc : Nat \rightarrow Nat

{-# BUILTIN NATURAL Nat #-}

{-# BUILTIN ZERO zero #-}

{-# BUILTIN SUC suc #-}

length : \{X: Set\} \rightarrow List X \rightarrow Nat

length \langle \rangle = zero

length (x, xs) = suc (length xs)
```

The number of c's in suc is a long standing area of open warfare.

Agda users tend to use lowercasevs-uppercase to distinguish things in Sets from things which are or manipulate Sets.

The pragmas let you use decimal numerals

Informally, we might state and prove something like

```
\forall fs, ss. \text{ length } fs = \text{length } ss \Rightarrow \text{length } (\text{zap } fs \ ss) = \text{length } fs
```

by structural induction [Burstall, 1969] on fs, say. Of course, we could just as well have concluded that length $(zap\ fs\ ss) = length\ ss$, and if we carry on zapping, we shall accumulate a multitude of expressions known to denote the same number.

What can we say about list concatenation? We may define addition.

How many ways to define $+_N$?

¹by which I mean, not to a computer

```
_{-+_{N-}}: Nat \rightarrow Nat \rightarrow Nat

zero +_{N} y = y

suc x +_{N} y = suc (x +_{N} y)
```

We may define concatenation.

```
\begin{array}{l} {}_{-}+_{\mathsf{L}}+_{-}: \{X: \mathsf{Set}\} \to \mathsf{List} \ X \to \mathsf{List} \ X \to \mathsf{List} \ X \\ \langle \rangle \qquad +_{\mathsf{L}}+ \ ys \ = \ ys \\ (x,xs) \ +_{\mathsf{L}}+ \ ys \ = \ x, (xs \ +_{\mathsf{L}}+ \ ys) \end{array}
```

It takes a proof by induction (and a convenient definition of $+_N$) to note that

```
length (xs + L + ys) = \text{length } xs + N \text{ length } ys
```

Matters get worse if we try to work with matrices as lists of lists (a matrix is a column of rows, say). How do we express rectangularity? Can we define a function to compute the dimensions of a matrix? Do we want to? What happens in degenerate cases? Given m, n, we might at least say that the outer list has length m and that all the inner lists have length n. Talking about matrices gets easier if we imagine that the dimensions are prescribed—to be checked, not measured.

1.0.1 Peano Exercises

Exercise 1.1 (Go Forth and Multiply!) Given addition, implement multiplication.

```
_{-}\times_{N-}: \mathsf{Nat} \to \mathsf{Nat} \to \mathsf{Nat}
```

Exercise 1.2 (Subtract with Dummy) *Implement subtraction, with a nasty old dummy return when you take a big number from a small one.*

```
_{-N-}: Nat \rightarrow Nat \rightarrow Nat
```

Exercise 1.3 (Divide with a Duplicate) *Implement division. Agda won't let you do repeated subtraction directly (not structurally decreasing), but you can do something sensible (modulo the dummy) like this:*

```
\begin{array}{ll} -\div_{\mathsf{N}-} : \mathsf{Nat} \to \mathsf{Nat} \to \mathsf{Nat} \\ x \div_{\mathsf{N}} d = \mathsf{help} \ x \ d \ \mathsf{where} \\ \mathsf{help} : \mathsf{Nat} \to \mathsf{Nat} \to \mathsf{Nat} \\ \mathsf{help} \ x \ e = & -- \{ !! \} \end{array}
```

You can recursively peel sucs from e one at a time, with the original d still in scope.

1.1 Vectors

Here are lists, indexed by numbers which happen to measure their length: these Agda allows over- are known in the trade as *vectors*.

```
\begin{array}{lll} \operatorname{\mathbf{data}} \operatorname{Vec} \left( X : \operatorname{Set} \right) : \operatorname{\mathsf{Nat}} \to \operatorname{\mathsf{Set}} \operatorname{\mathbf{where}} \\ & \langle \rangle & : & \operatorname{\mathsf{Vec}} X \operatorname{\mathsf{zero}} \\ & -, - : \left\{ n : \operatorname{\mathsf{Nat}} \right\} \to X \to \operatorname{\mathsf{Vec}} X \ n \to \operatorname{\mathsf{Vec}} X \ (\operatorname{\mathsf{suc}} n) \\ \\ \operatorname{\mathsf{vap}} : \left\{ n : \operatorname{\mathsf{Nat}} \right\} \left\{ S \ T : \operatorname{\mathsf{Set}} \right\} \to \operatorname{\mathsf{Vec}} \left( S \to T \right) \ n \to \operatorname{\mathsf{Vec}} S \ n \to \operatorname{\mathsf{Vec}} T \ n \\ \operatorname{\mathsf{vap}} \left\langle \right\rangle & \langle \rangle & = \left\langle \right\rangle \\ \operatorname{\mathsf{vap}} \left( f, fs \right) \left( s, ss \right) & = f \ s, \operatorname{\mathsf{vap}} fs \ ss \\ \end{array}
```

Agda allows overloading of constructors, as its approach to typechecking is of a bidirectional character

Might want to say something about head and tail, and about how coverage checking works anyway.

Not greatly enamoured of $S\ T$: Set notation, but there it

1.1. VECTORS 5

vec is an example of a function with an indexing argument that is usually inferrable, but never irrelevant.

By now, you may have noticed the proliferation of listy types.

```
\mathsf{vec} : \{ n : \mathsf{Nat} \} \{ X : \mathsf{Set} \} \to X \to \mathsf{Vec} \ X \ n
         vec \{zero\} \quad x = \langle \rangle
         vec {suc n} x = x, vec x
          \_+_{V}+_{\_}: \{m \ n : \mathsf{Nat}\} \{X : \mathsf{Set}\} \to \mathsf{Vec} \ X \ m \to \mathsf{Vec} \ X \ n \to \mathsf{Vec} \ X \ (m +_{\mathsf{N}} \ n)
          \langle \rangle +\vee+ ys = ys
         (x, xs) + + + ys = x, (xs + + ys)
                                                                                                                                                                                                                                                                                                                                                             Here's a stinker. Of
                                                                                                                                                                                                                                                                                                                                                              course, you can rejig
        \mathsf{vrevapp} \,:\, \{m\ n\ :\, \mathsf{Nat}\}\, \{X\ :\, \mathsf{Set}\} \to \mathsf{Vec}\, X\ m \to \mathsf{Vec}\, X\ n \to \mathsf{Vec}\, X\ (m\ +_{\mathsf{N}}\ n) \ n \to \mathsf{Nat}\}\, \{X\ :\, \mathsf{Set}\} \to \mathsf{Vec}\, X\ n 
        vrevapp ()
                                                                       ys = ys
                                                                                                                                                                                                                                                                                                                                                              sive and make +_V+
                                                                                                                                                                                                                                                                                                                                                             a stinker.
         vrevapp (x, xs) ys = \text{vrevapp } xs (x, ys)
                                                                                                                                                                                                                                                                                                                                                             Which other things
This is the 'traverse' function from the 'idiom paper' []
                                                                                                                                                                                                                                                                                                                                                             work badly? Filter?
                                                                                                                                                                                                                                                                                                                                                             I wanted to make _/_
         vtraverse : \{F: \mathsf{Set} \to \mathsf{Set}\} \to
                                                                                                                                                                                                                                                                                                                                                             left-associative, but
                                                          (\{X\,:\,\mathsf{Set}\}\to X\to F\;X)\to
                                                                                                                                                                                                                                                                                                                                                             no such luck.
                                                          (\{S\ T\ :\ \mathsf{Set}\} \to F\ (S \to T) \to F\ S \to F\ T) \to
                                                          \{n : \mathsf{Nat}\}\{X \mid Y : \mathsf{Set}\} \rightarrow
                                                          (X \to F \ Y) \to \mathsf{Vec} \ X \ n \to F \ (\mathsf{Vec} \ Y \ n)
        vtraverse pure \_/\_f \langle \rangle = pure \langle \rangle
         vtraverse pure_{-}/_{-}f(x,xs) = (pure_{-},_{-}/_{f}x) / vtraverse pure_{-}/_{-}fxs
                                                                                                                                                                                                                                                                                                                                                              When would be a
                                                                                                                                                                                                                                                                                                                                                             good time to talk
        X: \{X: \mathsf{Set}\} \to X \to X
                                                                                                                                                                                                                                                                                                                                                              about
                                                                                                                                                                                                                                                                                                                                                                                                      universe
        x = x
                                                                                                                                                                                                                                                                                                                                                             polymorphism?
         K: \{X \mid Y : \mathsf{Set}\} \to X \to Y \to X
         \kappa x y = x
                                                                                                                                                                                                                                                                                                                                                             Why is Y undeter-
                                                                                                                                                                                                                                                                                                                                                              mined?
         vsum : \{n : \mathsf{Nat}\} \to \mathsf{Vec} \; \mathsf{Nat} \; n \to \mathsf{Nat}
```

1.1.1 Matrix Exercises

Let us define an m by n matrix to be a vector of m rows, each length n.

```
\begin{array}{ll} \mathsf{Matrix} \, : \, \mathsf{Nat} \to \mathsf{Nat} \to \mathsf{Set} \to \mathsf{Set} \\ \mathsf{Matrix} \, m \, \, n \, \, X \, = \, \mathsf{Vec} \, (\mathsf{Vec} \, X \, n) \, \, m \end{array}
```

vsum = vtraverse (κ zero) $_{-}+_{N-} \{ Y = Nat \} _{I}$

Exercise 1.4 (Matrices are Applicative) *Show that* Matrix m n *can be equipped with operations analogous to* vec *and* vap.

```
\begin{array}{l} \mathsf{vvec} \ : \ \{m \ n \ : \ \mathsf{Nat}\} \ \{X \ : \ \mathsf{Set}\} \to X \to \mathsf{Matrix} \ m \ n \ X \\ \mathsf{vvap} \ : \ \{m \ n \ : \ \mathsf{Nat}\} \ \{S \ T \ : \ \mathsf{Set}\} \to \\ & \mathsf{Matrix} \ m \ n \ (S \to T) \to \mathsf{Matrix} \ m \ n \ S \to \mathsf{Matrix} \ m \ n \ T \end{array}
```

which, respectively, copy a given element into each position, and apply functions to arguments in corresponding positions.

Exercise 1.5 (Matrix Addition) *Use the applicative interface for* Matrix *to define their elementwise addition.*

```
\_+_{\mathsf{M}}\_: \{m\ n\ : \mathsf{Nat}\} \to \mathsf{Matrix}\ m\ n\ \mathsf{Nat} \to \mathsf{Matrix}\ m\ n\ \mathsf{Nat} \to \mathsf{Matrix}\ m\ n\ \mathsf{Nat}
```

Exercise 1.6 (Matrix Transposition) *Use* vtraverse to give a one-line definition of matrix transposition.

```
\mathsf{transpose} \,:\, \{\, m \,\, n \,\,:\,\, \mathsf{Nat} \} \,\{\, X \,\,:\,\, \mathsf{Set} \,\} \,\rightarrow\, \mathsf{Matrix} \,\, m \,\, n \,\, X \,\rightarrow\, \mathsf{Matrix} \,\, n \,\, m \,\, X
```

Exercise 1.7 (Identity Matrix) Define a function

```
idMatrix : \{n : Nat\} \rightarrow Matrix \ n \ Nat
```

Exercise 1.8 (Matrix Multiplication) *Define matrix multiplication. There are lots of ways to do this. Some involve defining scalar product, first.*

```
\_\times_{\mathsf{M}}\_: \{l\ m\ n\ : \mathsf{Nat}\} \to \mathsf{Matrix}\ l\ m\ \mathsf{Nat} \to \mathsf{Matrix}\ m\ n\ \mathsf{Nat} \to \mathsf{Matrix}\ l\ n\ \mathsf{Nat}
```

1.1.2 Unit and Sigma types

record 1: Set where constructor $\langle \rangle$

Why do this with records?

```
open 1 public  \begin{array}{l} u0:1\\ u0=\langle\rangle\\ u1:1\\ u1=\operatorname{record}\left\{\right\}\\ u2:1\\ u2=-\\ \end{array}   \begin{array}{l} \operatorname{record}\Sigma\left(S:\operatorname{Set}\right)\left(T:S\to\operatorname{Set}\right):\operatorname{Set}\text{ where }\\ \operatorname{constructor}_{-,-}\\ \operatorname{field}\\ \operatorname{fst}:S\\ \operatorname{snd}:T\operatorname{fst} \end{array}
```

The **field** keyword declares fields, we can also add 'manifest' fields.

1.1.3 Apocrypha

open ∑ public

 $_\times_: \mathsf{Set} \to \mathsf{Set} \to \mathsf{Set}$ $S \times T = \Sigma S \lambda _ \to T$

You would not invent dependent pattern matching if vectors were your only example.

The definition is logically the same, why are the programs noisier?

```
\begin{array}{lll} \operatorname{VecR}: \operatorname{Set} \to \operatorname{Nat} \to \operatorname{Set} \\ \operatorname{VecR} X \operatorname{zero} &= 1 \\ \operatorname{VecR} X \left( \operatorname{suc} n \right) &= X \times \operatorname{VecR} X n \\ \\ \operatorname{vconcR}: \left\{ m \ n : \operatorname{Nat} \right\} \left\{ X : \operatorname{Set} \right\} \to \\ \operatorname{VecR} X \ m \to \operatorname{VecR} X \ n \to \operatorname{VecR} X \left( m +_{\operatorname{N}} n \right) \\ \operatorname{vconcR} \left\{ \operatorname{zero} \right\} & \langle \rangle & ys = ys \\ \operatorname{vconcR} \left\{ \operatorname{suc} m \right\} \left( x, xs \right) ys &= x, \operatorname{vconcR} \left\{ m \right\} xs \ ys \\ \end{array}
```

1.2. FINITE SETS 7

```
data = {X : Set} (x : X) : X \to Set where
    \langle \rangle : x = x
\mathsf{len} \,:\, \{X\,:\, \mathsf{Set}\} \to \mathsf{List}\, X \to \mathsf{Nat}
len \langle \rangle = zero
len (x, xs) = suc (len xs)
                                                                                                                                     Agda's \lambda scopes
                                                                                                                                     rightward as far as
\mathsf{VecP}\;:\;\mathsf{Set}\to\mathsf{Nat}\to\mathsf{Set}
                                                                                                                                     possible, reducing
                                                                                                                                     bracketing. Even
VecP X \ n = \Sigma \text{ (List } X \text{) } \lambda \ xs \rightarrow \text{len } xs == n
                                                                                                                                     newer fancy bind-
                                                                                                                                     ing sugar might
                                                                                                                                     make this prettier
\mathsf{vnil} : \{X : \mathsf{Set}\} \to \mathsf{VecP} \ X \ \mathsf{zero}
                                                                                                                                     still.
vnil = \langle \rangle, \langle \rangle
                                                                                                                                     It's already getting
                                                                                                                                     bad here, but we can
vcons : \{X : \mathsf{Set}\} \{n : \mathsf{Nat}\} \to X \to \mathsf{VecP} \ X \ n \to \mathsf{VecP} \ X \ (\mathsf{suc} \ n)
                                                                                                                                     match p against \langle \rangle
                                                                                                                                     and complete.
vcons x(xs, p) = (x, xs), -- \{!!\}
                                                                                                                                     But this really is
                                                                                                                                     toxic.
\mathsf{vapP} : \{ n : \mathsf{Nat} \} \{ S \ T : \mathsf{Set} \} \to
             VecP (S \rightarrow T) n \rightarrow VecP S n \rightarrow VecP T n
\mathsf{vapP}\left(\langle\rangle,\langle\rangle\right) \qquad (\langle\rangle,\langle\rangle) \qquad = \,\langle\rangle,\langle\rangle
\mathsf{vapP}\left((f,fs),\langle\rangle\right)((s,ss),p) = (f\ s,\mathsf{vap}\ (fs,?)\ (ss,?)),?
```

1.2 Finite Sets

If we know the size of a vector, can we hope to project from it safely? Here's a family of *finite sets*, good to use as indices into vectors.

```
\begin{array}{lll} \mathbf{data} \; \mathsf{Fin} \; : \; \mathsf{Nat} \to \mathsf{Set} \; \mathbf{where} \\ & \mathsf{zero} \; : \; \{n \; : \; \mathsf{Nat}\} \to & \mathsf{Fin} \; (\mathsf{suc} \; n) \\ & \mathsf{suc} \; : \; \{n \; : \; \mathsf{Nat}\} \to (i \; : \; \mathsf{Fin} \; n) \to \mathsf{Fin} \; (\mathsf{suc} \; n) \\ & foo \; : \; \{X \; : \; \mathsf{Set}\} \; \{n \; : \; \mathsf{Nat}\} \to \mathsf{Fin} \; (\mathsf{zero} \; +_{\mathsf{N}} \; \mathsf{zero}) \to X \\ & foo \; () \end{array}
```

Finite sets are sets of bounded numbers. One thing we may readily do is forget the bound.

Do you resent writing this function? You should.

```
fog : \{n : \mathsf{Nat}\} \to \mathsf{Fin} \ n \to \mathsf{Nat}
fog zero = zero
fog (suc i) = suc (fog i)
```

Now let's show how to give a total projection from a vector of known size.

 $\begin{array}{lll} \mathsf{vproj} \,:\, \{\, n \,:\, \mathsf{Nat} \} \, \{X \,:\, \mathsf{Set} \} \to \mathsf{Vec} \, X \,\, n \to \mathsf{Fin} \,\, n \to X \\ \mathsf{vproj} \,\, \langle \rangle \,\, () \\ \mathsf{vproj} \,\, (x, xs) \,\, \mathsf{zero} &= \, x \\ \mathsf{vproj} \,\, (x, xs) \,\, (\mathsf{suc} \,\, i) &= \,\, \mathsf{vproj} \,\, xs \,\, i \end{array}$

Suppose we want to project at an index not known to be suitably bounded. How might we check the bound? We shall return to that thought, later.

Fanny. We could also swap the arguments around.

Here's our first Aunt

It's always possible to give enough Aunt Fannies to satisfy the coverage checker.

1.2.1 Renamings

We'll shortly use Fin to type bounded sets of de Bruijn indices. Functions from one finite set to another will act as 'renamings'.

Extending the context with a new assumption is sometimes known as 'weakening': making more assumptions weakens an argument. Suppose we have a function from Fin m to Fin n, renaming variables, as it were. How should weakening act on this function? Can we extend the function to the sets one larger, mapping the 'new' source zero to the 'new' target zero? This operation shows how to push a renaming under a binder.

Categorists, what should we prove about weaken?

One operation we'll need corresponds to inserting a new variable somewhere in the context. This operation is known as 'thinning'. Let's define the order-preserving injection from $\operatorname{Fin} n$ to $\operatorname{Fin} (\operatorname{suc} n)$ which misses a given element

```
\begin{array}{ll} \mathsf{thin} \ : \ \{n \ : \ \mathsf{Nat}\} \to \mathsf{Fin} \ (\mathsf{suc} \ n) \to \mathsf{Fin} \ n \to \mathsf{Fin} \ (\mathsf{suc} \ n) \\ \mathsf{thin} & \mathsf{zero} &= \mathsf{suc} \\ \mathsf{thin} \ \{\mathsf{zero}\} & (\mathsf{suc} \ ()) \\ \mathsf{thin} \ \{\mathsf{suc} \ n\} \ (\mathsf{suc} \ i) &= \mathsf{weaken} \ (\mathsf{thin} \ i) \end{array}
```

1.2.2 Finite Set Exercises

Exercise 1.9 (Tabulation) *Invert* vproj. *Given a function from a* Fin set, show how to construct the vector which tabulates it.

```
vtab : \{n : \mathsf{Nat}\} \{X : \mathsf{Set}\} \to (\mathsf{Fin}\ n \to X) \to \mathsf{Vec}\ X\ n
```

Exercise 1.10 (Plan a Vector) Show how to construct the 'plan' of a vector—a vector whose elements each give their own position, counting up from zero.

```
vplan : \{n : \mathsf{Nat}\} \to \mathsf{Vec}(\mathsf{Fin}\ n)\ n
```

Exercise 1.11 (Max a Fin) Every nonempty finite set has a smallest element zero and a largest element which has as many sucs as allowed. Construct the latter

```
\max : \{n : \mathsf{Nat}\} \to \mathsf{Fin} (\mathsf{suc} \ n)
```

Exercise 1.12 (Embed, Preserving fog) *Give the embedding from one finite set to the next which preserves the numerical value given by* fog.

```
emb : \{n : \mathsf{Nat}\} \to \mathsf{Fin}\ n \to \mathsf{Fin}\ (\mathsf{suc}\ n)
```

Exercise 1.13 (Thickening) Construct thick i the partial inverse of thin i. You'll need

Which operations on Maybe will help? Discover and define them as you implement:

```
thick : \{n : \mathsf{Nat}\} \to \mathsf{Fin}(\mathsf{suc}\,n) \to \mathsf{Fin}(\mathsf{suc}\,n) \to \mathsf{Maybe}(\mathsf{Fin}\,n)
```

Note that thick acts as an inequality test.

1.2. FINITE SETS 9

Exercise 1.14 (Order-Preserving Injections) Define an inductive family

 $\mathsf{OPI}\,:\,\mathsf{Nat}\to\mathsf{Nat}\to\mathsf{Set}$

such that $\mathsf{OPI}\ m\ n$ gives a unique first-order representation to exactly the order-preserving injections from $\mathsf{Fin}\ m$ to $\mathsf{Fin}\ n$, and give the functional interpretation of your data. Show that $\mathsf{OPI}\ is\ closed\ under\ identity\ and\ composition.$

Chapter 2

Lambda Calculus with de Bruijn Indices

I'm revisiting chapter 7 of my thesis here.

Here are the λ -terms with n available de Bruijn indices [de Bruijn, 1972].

```
data Tm(n : Nat) : Set where
      var : Fin n \rightarrow
       \$ : Tm n \to \text{Tm } n \to \text{Tm } n
      lam : Tm (suc n) \rightarrow
   infixl 6 $
Which operations work?
Substitute for zero?
                                                                                                                          How many different
                                                                                                                          kinds of trouble are
   \mathsf{sub0} : \{ n : \mathsf{Nat} \} \to \mathsf{Tm} \ n \to \mathsf{Tm} \ (\mathsf{suc} \ n) \to \mathsf{Tm} \ n
   sub0 s (var zero)
   sub0 s (var (suc i)) = var i
   sub0 s (f \$ a) = sub0 s f \$ sub0 s a
   sub0 s (lam b)
                              = lam (sub0 ? b)
Simultaneous substitution?
                                                                                                                          Notoriously
                                                                                                                          structurally recur-
   ssub : \{m \ n : \mathsf{Nat}\} \to (\mathsf{Fin} \ m \to \mathsf{Tm} \ n) \to \mathsf{Tm} \ m \to \mathsf{Tm} \ n
   \operatorname{ssub} \sigma (\operatorname{var} i) = \sigma i
   \operatorname{ssub} \sigma (f \$ a) = \operatorname{ssub} \sigma f \$ \operatorname{ssub} \sigma a
   ssub \{m\} \{n\} \sigma (lam b) = lam (ssub \sigma b) where
      \sigma : \mathsf{Fin} (\mathsf{suc} \ m) \to \mathsf{Tm} (\mathsf{suc} \ n)
                  = var zero
      \sigma (suc i) = ssub (\lambda i \rightarrow \text{var} (\text{suc } i)) (\sigma i)
```

At this point, Thorsten Altenkirch and Bernhard Reus [Altenkirch and Reus, 1999] reached for the hammer of wellordering, but there's a cheaper way to get out of the jam.

2.1 Simultaneous Renaming and Substitution

You can define simultaneous renaming really easily.

```
wkr : \{m \ n : \mathsf{Nat}\} \to (\mathsf{Fin} \ m \to \mathsf{Fin} \ n) \to \mathsf{Fin} \ (\mathsf{suc} \ m) \to \mathsf{Fin} \ (\mathsf{suc} \ n) wkr \rho \ \mathsf{zero} = \mathsf{zero}
```

```
\begin{array}{ll} \mathsf{wks} \,:\, \{m\; n \,:\, \mathsf{Nat}\} \to (\mathsf{Fin}\; m \to \mathsf{Tm}\; n) \to \mathsf{Fin}\; (\mathsf{suc}\; m) \to \mathsf{Tm}\; (\mathsf{suc}\; n) \\ \mathsf{wks}\; \sigma\; \mathsf{zero} &=\; \mathsf{var}\; \mathsf{zero} \\ \mathsf{wks}\; \sigma\; (\mathsf{suc}\; i) &=\; \mathsf{ren}\; \mathsf{suc}\; (\sigma\; i) \\ \mathsf{sub}\; :\, \{m\; n \,:\, \mathsf{Nat}\} \to (\mathsf{Fin}\; m \to \mathsf{Tm}\; n) \to \mathsf{Tm}\; m \to \mathsf{Tm}\; n \\ \mathsf{sub}\; \sigma\; (\mathsf{var}\; i) &=\; \sigma\; i \\ \mathsf{sub}\; \sigma\; (f\; \$\; a) &=\; \mathsf{sub}\; \sigma\; f\; \$\; \mathsf{sub}\; \sigma\; a \\ \mathsf{sub}\; \sigma\; (\mathsf{lam}\; b) &=\; \mathsf{lam}\; (\mathsf{sub}\; (\mathsf{wks}\; \sigma)\; b) \end{array}
```

How repetitive! Let's abstract out the pattern.

```
record Kit (I : \mathsf{Nat} \to \mathsf{Set}) : \mathsf{Set} where
     constructor mkKit
     field
          \mathsf{mkv} : \{ n : \mathsf{Nat} \} \to \mathsf{Fin} \ n \to I \ n
          \mathsf{mkt} : \{ n : \mathsf{Nat} \} \to I \ n \to \mathsf{Tm} \ n
          \mathsf{wki} \; : \; \{ \, n \, : \, \mathsf{Nat} \, \} \to I \; n \to I \; (\mathsf{suc} \; n)
open Kit public
\mathsf{wk} : \{I : \mathsf{Nat} \to \mathsf{Set}\} \to \mathsf{Kit} I \to \{m \ n : \mathsf{Nat}\} \to \mathsf{Nat}\}
            (\operatorname{\mathsf{Fin}}\ m \to I\ n) \to \operatorname{\mathsf{Fin}}\ (\operatorname{\mathsf{suc}}\ m) \to I\ (\operatorname{\mathsf{suc}}\ n)
\mathsf{wk}\ k\ \tau\ \mathsf{zero} \qquad =\ \mathsf{mkv}\ k\ \mathsf{zero}
\mathsf{wk}\ k\ \tau\ (\mathsf{suc}\ i) = \mathsf{wki}\ k\ (\tau\ i)
\mathsf{act} \,:\, \{I \,:\, \mathsf{Nat} \to \mathsf{Set}\} \to \mathsf{Kit}\, I \to \{m\,\, n \,:\, \mathsf{Nat}\} \to
            (\operatorname{\mathsf{Fin}}\ m \to I\ n) \to \operatorname{\mathsf{Tm}}\ m \to \operatorname{\mathsf{Tm}}\ n
act k \tau (var i) = mkt k (\tau i)
act k \tau (f \$ a) = act k \tau f \$ act k \tau a
\mathsf{act}\ k\ \tau\ (\mathsf{lam}\ b)\ =\ \mathsf{lam}\ (\mathsf{act}\ k\ (\mathsf{wk}\ k\ \tau)\ b)
```

2.1.1 Exercises

Exercise 2.1 (Renaming Kit) *Define the renaming kit.*

```
renk: Kit Fin
```

Exercise 2.2 (Substitution Kit) *Define the substitution kit.*

```
subk: Kit Tm
```

```
Exercise 2.3 (Substitute zero) sub0 : \{n : \mathsf{Nat}\} \to \mathsf{Tm}\ n \to \mathsf{Tm}\ (\mathsf{suc}\ n) \to \mathsf{Tm}\ n
```

Exercise 2.4 (Reduce One) *Define a function to contract the leftmost redex in a* λ *-term, if there is one.*

```
leftRed : \{n : \mathsf{Nat}\} \to \mathsf{Tm} \ n \to \mathsf{Maybe} \ (\mathsf{Tm} \ n)
```

Exercise 2.5 (Complete Development) *Show how to compute the complete development of a* λ -term, contracting all its visible redexes in parallel (but not the redexes which thus arise).

```
\mathsf{develop} \,:\, \{\, n \,:\, \mathsf{Nat}\, \} \to \mathsf{Tm}\,\, n \to \mathsf{Tm}\,\, n
```

Exercise 2.6 (Gasoline Alley) Write an iterator, computing the n-fold self-composition of an endofunction, effectively interpreting each Nat as its corresponding Church numeral.

```
iterate : Nat \rightarrow \{X: \mathsf{Set}\} \rightarrow (X \rightarrow X) \rightarrow X \rightarrow X
```

You can use iterate and develop to run λ -terms for as many steps as you like, as long as you are modest in your likes.

Exercise 2.7 (Another Substitution Recipe) It occurred to me at time of writing that one might cook substitution differently. Using abacus-style addition

be the type of substitions which can be weakened. Define

```
\mathsf{subw} \; : \; \{ m \; n \; : \; \mathsf{Nat} \} \to \mathsf{Sub} \; m \; n \to \mathsf{Tm} \; m \to \mathsf{Tm} \; n
```

Now show how to turn a renaming into a Sub.

```
renSub : \{m \ n : \mathsf{Nat}\} \to (\mathsf{Fin} \ m \to \mathsf{Fin} \ n) \to \mathsf{Sub} \ m \ n
```

Finally, show how to turn a simultaneous substitution into a Sub.

```
subSub : \{m \ n : Nat\} \rightarrow (Fin \ m \rightarrow Tm \ n) \rightarrow Sub \ m \ n
```

2.1.2 How to Hide de Bruijn Indices

```
\max : \{n : \mathsf{Nat}\} \to \mathsf{Fin} (\mathsf{suc} \ n)
max \{zero\} = zero
\max \{ suc n \} = suc (\max \{ n \})
embed : \{n : \mathsf{Nat}\} \to \mathsf{Fin}\ n \to \mathsf{Fin}\ (\mathsf{suc}\ n)
embed zero
                    = zero
embed (suc n) = suc (embed n)
shifty: (m : Nat) \{ n : Nat \} \rightarrow Fin (suc (m + N n))
shifty zero
                 = max
shifty (suc m) = embed (shifty m)
lambda : \{m : \mathsf{Nat}\} \rightarrow
              ((\{n : \mathsf{Nat}\} \to \mathsf{Tm} (\mathsf{suc} (m +_{\mathsf{N}} n))) \to \mathsf{Tm} (\mathsf{suc} m)) \to
lambda \{m\} f = \text{lam} (f \lambda \{n\} \rightarrow \text{var} (\text{shifty } m \{n\}))
myTest: Tm zero
myTest = lambda \lambda f \rightarrow lambda \lambda x \rightarrow f \$ (f \$ x)
```

2.1.3 Simply Typed Lambda Calculus

Altenkirch and Reus carry on to develop simultaneous type-preserving substitution for the *simply-typed* λ -calculus. Let's see how.

```
infixr \not 4 \triangleright \bot
infixr \not 3 \vdash \bot
infixr \not 3 \dashv
data Ty : Set where
 \iota : Ty
 \triangleright \bot : (S T : Ty) \rightarrow Ty
```

I'll have a bunch of variations, so it will help if I make context a general type of snoc-list.

```
data Context (X : Set) : Set where \langle \rangle : Context X \rightarrow (G : Context X) (S : X) <math>\rightarrow Context X
```

Variables become typed references into the context.

Types reflect the typing rules (which are syntax-directed). I exploit comment syntax to write a suggestive line of dashes in the relevant places. I have not managed to persuade <code>lhs2TeX</code> to achieve that.

```
data \vdash: Context Ty \rightarrow Ty \rightarrow Set where

var : \forall { G T } (x:G\dashv T)
\rightarrow --
G \vdash T

-- \lambda-abstraction extends the context

lam : \forall { G S T } (b:G,S\vdash T)
\rightarrow --
G \vdash S \rhd T

-- application demands a type coincidence

$\frac{\$\$}. : \forall { G S T } (f:G\vdash S \rhd T) (s:G\vdash S)
\rightarrow --
G \vdash T
```

Implementing an evaluator is an exercise in denotational semantics. First, explain what types mean: functions are...functions!

Interpret contexts as types of environments.

Interpret variables as projections from environments.

Interpret terms, plumbing the environment.

Here's an example term. You may notice that Agda cannot fully infer its type, but it is still willing to run it.

```
example : \langle \rangle \vdash \_ example = (lam (var zero)) $ lam (var zero)
```

2.1.4 An Exercise

Exercise 2.8 (Simultaneous Substitution) *Using a technique of your choice and implementing auxiliary functions as needed, show how to adapt our implementation of scopesafe substitution to type-safe substitution. Define*

```
\begin{array}{c} \mathsf{tsub} \,:\, \forall \, \big\{\varGamma \, \Delta\big\} \to (\forall \, \big\{\, T\,\big\} \to \varGamma \dashv T \to \varDelta \vdash T) \\ \to (\forall \, \big\{\, T\,\big\} \to \varGamma \vdash T \to \varDelta \vdash T) \end{array}
```

2.1.5 Robbing Peter to Pay Paul

Based on Paul Blain Levy's *call-by-push-value* calculus, here's a variation on the simply typed λ -calculus for you to play with and extend.

Types are separated into *value* types for 'being' and *computation* types for 'doing'. I've supplied some primitive value types.

```
mutualdata VTy: Set where-- value types for ways of beingUNK: CTy \rightarrow VTy-- a suspended computation is a valueONE TWO: VTy-- primitive value typesdata CTy: Set where-- computation types for ways of doingEFF: VTy \rightarrow CTy-- making a value by doing effects\triangleright: VTy \rightarrow CTy \rightarrow CTy-- abstract a computationdata 2: Set where tt ff: 2
```

You may wish to add more value types.

To give semantics to these types, we'll need a type of command-response trees. They make a monad. Here I've added a command toss, whose 'ML type' would be $1 \rightarrow 2$, but it's really tossing a coin.

```
 \begin{array}{lll} \textbf{data} \ \mathsf{Eff} \ (X : \mathsf{Set}) : \mathsf{Set} \ \textbf{where} \\ & \mathsf{ret} \ : \ X \to & \mathsf{Eff} \ X \\ & \mathsf{toss} : \ 1\!\!1 \to (2\!\!2 \to \mathsf{Eff} \ X) \to \mathsf{Eff} \ X \\ \end{array}
```

The ret constructor puts values at the leaves of the tree. Meanwhile, the 'bind', >>= acts like tree-grafting, pasting new command-response strategies onto the leaves of old.

Exercise 2.9 (Bind for tossing Trees) *Define* $> \!\!\!> to$ *graft strategy trees together.*

```
\begin{array}{ll} - > > - : \forall \left\{ S \; T \right\} \to \mathsf{Eff} \; S \to \left( S \to \mathsf{Eff} \; T \right) \to \mathsf{Eff} \; T \\ \mathsf{ret} \; x & > > = f = f \; x \\ \mathsf{toss} \; u \; k > > = f = \mathsf{toss} \; u \; \lambda \; b \to k \; b > = f \end{array}
```

You may wish to modify the signature of operations available, but the general structure of $\mathsf{Eff}\ X$ trees will remain the same, with nodes carry commands and edges branching over possible responses.

To give you a better clue of what's going on, let me define the semantics of these types. Values are, er, values in the given type. By contrast, computations are Kleisli arrows—operations which produce Eff-strategies to compute a Return value, given a tuple of Args.

mutual

We have separated being and doing. There are two categories at work

• [-]CT gives the subcategory of Set containing just those named by elements of CTy, with morphisms given by

```
\begin{array}{lll} \_ \to_{\mathsf{C} -} : \; \mathsf{CTy} \to \mathsf{CTy} \to \mathsf{Set} \\ C \; \to_{\mathsf{C}} \; C' \; = \; [ \![ \; C \; ] \!]_{\mathsf{CT}} \to [ \![ \; C' \; ] \!]_{\mathsf{CT}} \end{array}
```

and the usual functional identity and composition;

• we have the subcategory of Eff's Kleisli category induced by $[\![_]\!]_{VT}$, with objects named by elements of VTy and morphisms being

with ret as the identity and >= inducing a composition

```
\_\circ_{\mathsf{V}\_}: \{R\ S\ T\ : \mathsf{Set}\} \to (S \to \mathsf{Eff}\ T) \to (R \to \mathsf{Eff}\ S) \to R \to \mathsf{Eff}\ T
f \circ_{\mathsf{V}} g = \lambda \ r \to g \ r \ggg f
```

You may wish to check that this composition is associative and absorbs identity on either side.

Exercise 2.10 (Functorial EFF and UNK) *Show that the EFF and UNK constructors, which turn value types into computation types and vice versa, extend to functors.*

$$\mathsf{EFF}^{\$} : \{ V \ V' : \mathsf{VTy} \} \to (V \ \to_{\mathsf{V}} \ V') \to (\mathsf{EFF} \ V \ \to_{\mathsf{C}} \ \mathsf{EFF} \ V')$$

$$\mathsf{UNK}^{\$} : \{ C \ C' : \mathsf{CTy} \} \to (C \ \to_{\mathsf{C}} \ C') \to (\mathsf{UNK} \ C \ \to_{\mathsf{V}} \ \mathsf{UNK} \ C')$$

Feel free to prove that identity and composition are suitably respected.

Exercise 2.11 (Up the Adjunction) *Now show*

in such a way that the two are mutually inverse.

We've split our monad into an adjunction, connecting distinct notions of value and computation.

Now, let's have some language.

```
mutual
    data Value (\Gamma: Context VTy) : VTy \rightarrow Set where
        \mathsf{var} : \forall \{V\} \to \Gamma \dashv V \to
                                                                     Value \Gamma V
        \langle \rangle :
                                                                      Value \Gamma ONE
                                                                     Value \Gamma TWO
        tt ff :
        |\bot|: \forall \{C\} \rightarrow \mathsf{Compt}\ \Gamma\ C \rightarrow \mathsf{Value}\ \Gamma\ (\mathsf{UNK}\ C)
    data Compt (\Gamma : Context \ VTy) : CTy \rightarrow Set \ where
                                                                                                                    Compt \Gamma (EFF TWO)
        lam : \forall \{V C\} \rightarrow \mathsf{Compt}(\Gamma, V) C \rightarrow
                                                                                                                    Compt \Gamma (V \triangleright C)
        \$ : \forall \{V C\} \rightarrow \mathsf{Compt} \ \Gamma \ (V \triangleright C) \rightarrow \mathsf{Value} \ \Gamma \ V \rightarrow \mathsf{Compt} \ \Gamma \ C
        \mathsf{ret} \ : \ \forall \ \{ \ V \ \} \quad \to \mathsf{Value} \ \varGamma \ \stackrel{\frown}{V} \to
                                                                                                                    Compt \Gamma (EFF V)
        bind : \forall \{ V C \} \rightarrow \mathsf{Compt} \ \Gamma \ (\mathsf{EFF} \ V) \rightarrow \mathsf{Compt} \ (\Gamma, V) \ C \rightarrow
                                                                                                                    Compt \Gamma C
               : \ \forall \ \{ \ C \ \} \qquad \rightarrow \mathsf{Value} \ \varGamma \ \mathsf{TWO} \rightarrow \mathsf{Compt} \ \varGamma \ C \rightarrow \mathsf{Compt} \ \varGamma \ C \rightarrow
                                                                                                                    Compt \Gamma C
```

Here are contexts, interpreted as environment types, with variables represented as value projections.

Now your turn.

Exercise 2.12 (Interpreter) *Define mutually recursive interpreters for values and computations. You should interpret* toss *via the* toss *constructor of* Eff.

mutual

Exercise 2.13 (Natural Numbers) *Extend the language with a* VTy *of natural numbers, adding* **zero** *and* **suc** *constructors to* Value *and an effectful primitive recursor to* Compt.

Exercise 2.14 (Input/Output) Extend Eff, and your extended language with get and put operators, respectively reading and writing natural numbers.

Exercise 2.15 (State) *Implement an interpreter for* Eff strategies, treating the get and put operations as reading and writing a Nat-valued state. Feel free to make toss work any way you like.

Next, an exercise received with gratitude from Peter Hancock.

Exercise 2.16 (Interlopers) Implement an operator which combines two communicating processes alice: Eff \mathbb{I} and bob: Eff X to make a single demand-driven Eff X process. Here's the plan: bob's activities should be prioritised; his puts should be put to the world, but his gets should come from alice's puts; alice should run only when bob needs input, and should get from the world; if alice terminates before bob returns an X, bob should get the rest of his inputs directly from the world.

Implement a similar but supply-driven combinator, connecting bob: Eff X and charlie: Eff 1, where charlie gets in the way of bob's puts.

2.1.6 Compare and Swap

Here's a little recursor for pairs of numbers, generalizing a pattern I learned from James McKinna.

```
\begin{array}{lll} \operatorname{commRec} \ : \ \{X \ : \ \mathsf{Set}\} \to (\mathsf{Nat} \to X) \to (X \to X) \to \mathsf{Nat} \to \mathsf{Nat} \to X \\ \operatorname{commRec} \ z \ s \ \mathsf{zero} & n & = \ z \ n \\ \operatorname{commRec} \ z \ s \ m & \mathsf{zero} & = \ z \ m \\ \operatorname{commRec} \ z \ s \ (\mathsf{suc} \ m) \ (\mathsf{suc} \ n) & = \ s \ (\mathsf{commRec} \ z \ s \ m \ n) \end{array}
```

Exercise 2.17 (Commutativity) *Show that* commRec *z s is commutative.*

```
commRecComm : \{X: \mathsf{Set}\}\ (z: \mathsf{Nat} \to X)\ (s: X \to X)\ (m\ n: \mathsf{Nat}) \to \mathsf{commRec}\ z\ s\ m\ n == \mathsf{commRec}\ z\ s\ n\ m
```

Exercise 2.18 (Arithmetic Operations) *Implement addition and multiplication by suitably instantiating* commRec. *Multiplication is a bit tricky: you may find that you need to compute an extra quantity, alongside the product, in order to make the recursion go through.*

Exercise 2.19 (Comparison Operations) *Implement maximum and minimum by suitably instantiating* commRec. *Implement the equality test*.

I finally gave in and defined the following operation to help with the next exercise. It's the 'uncurry' operation, but with a dependent type which effectively makes it the *dependent case analysis* principle for Σ A B: not only do you split a pair ab into pieces a and b, you also learn that ab is a, b. I write it as v as it depicts the splitting of one into two.

```
\mathbf{v}: \{A: \mathsf{Set}\} \{B: A \to \mathsf{Set}\} \{C: \Sigma A B \to \mathsf{Set}\} \to ((a:A) (b:B a) \to C (a,b)) \to -\mathsf{two} \text{ on top } (ab:\Sigma A B) \to C ab -\mathsf{one} \text{ below } \mathbf{v} f ab = f \text{ (fst } ab \text{) (snd } ab)
```

Exercise 2.20 (Compare-and-swap) *Use* commRec to implement cas, the operation which sorts a pair of numbers into increasing order.

```
cas : Nat \times Nat \to Nat \times Nat
```

But where is the λ -calculus? It's on its way. Here are today's *linear* types.

```
\begin{array}{lll} \textbf{data} \ \mathsf{LTy} \ : \ \mathsf{Set} \ \textbf{where} \\ & \mathsf{ONE} \ \mathsf{TWO} \ \mathsf{KEY} \ : & \mathsf{LTy} \\ & \mathsf{LIST} \ \mathsf{TREE} & : & \mathsf{LTy} \to \mathsf{LTy} \\ & -\!\!\!\!\!-\!\!\!\!-\!\!\!\!-\!\!\!\!-\!\!\!\!\!- \& \& & : \ \mathsf{LTy} \to \mathsf{LTy} \to \mathsf{LTy} \end{array}
```

Let's consider a *linear* context to be a list of Maybe-types which indicate availability.

```
LCx : Set
LCx = Context (Maybe LTy)
```

We can make a variable reference record the usage by indexing by contexts, before and after.

```
\begin{array}{lll} \textbf{data} \ \mathsf{LV} \ : \ \mathsf{LCx} \to \mathsf{LTy} \to \mathsf{LCx} \to \mathsf{Set} \ \textbf{where} \\ & \mathsf{zero} \ : \ \forall \ \{\varGamma \ T\} \to & \mathsf{LV} \ (\varGamma, \mathsf{yes} \ T) \ T \ (\varGamma, \mathsf{no}) \\ & \mathsf{suc} \ : \ \forall \ \{\varGamma_0 \ \varGamma_1 \ T \ S\} \to \mathsf{LV} \ \varGamma_0 \ T \ \varGamma_1 \to \mathsf{LV} \ (\varGamma_0, S) \ T \ (\varGamma_1, S) \\ \\ \textbf{data} \ \mathsf{LTm} \ : \ \mathsf{LCx} \to \mathsf{LTy} \to \mathsf{LCx} \to \mathsf{Set} \ \textbf{where} \\ & \mathsf{var} \ : \ \forall \ \{\varGamma_0 \ \varGamma_1 \ T\} \to \mathsf{LV} \ \varGamma_0 \ T \ \varGamma_1 \to \mathsf{LTm} \ \varGamma_0 \ T \ \varGamma_1 \\ & \mathsf{lam} \ : \ \forall \ \{\varGamma_0 \ \varGamma_1 \ S \ T\} \to \mathsf{LTm} \ (\varGamma_0, \mathsf{yes} \ S) \ T \ (\varGamma_1, \mathsf{no}) \to \mathsf{LTm} \ \varGamma_0 \ (S \multimap T) \ \varGamma_1 \\ & \$ \ : \ \forall \ \{\varGamma_0 \ \varGamma_1 \ \varGamma_2 \ S \ T\} \to \mathsf{LTm} \ \varGamma_0 \ (S \multimap T) \ \varGamma_1 \to \mathsf{LTm} \ \varGamma_1 \ S \ \varGamma_2 \to \mathsf{LTm} \ \varGamma_0 \ T \ \varGamma_1 \\ \end{array}
```

Sorry folks, I've got to stop preparing this exercise and prepare the lectures instead. I'll finish it later, but let me tell you where it's going. The plan is to deliver a domain-specific language for transforming containers which neither copy nor delete elements, so that a function of type LIST KEY — LIST KEY must deliver as output a permutation of its input. Equipped with compare-and-swap for KEY, one should be able to implement sorting functions, guaranteeing the permutation property by construction.

Chapter 3

Views

Views [Wadler, 1987] provide a way to give an alternative interface to an existing type.

We can write a program which transforms our original data to its alternative representation, but in the dependently typed setting, we may and we should get a little more. Let's see how.

Given some 'upper bound', a number u, we may check if any other number, n is below it or not, for example, to check if n may be used to index a vector of size u. However, a Boolean answer alone will not help, if our indexing function vproj demands an element of Fin u. We could define a function in Nat \rightarrow Maybe (Fin u) to compute n's representation in Fin u if it exists, but that simple type does not tell us what that representative has to do with n. Alternatively, we can express what it means for n to be *bounds-checkable*: it must be detectably either representable in Fin u, or u + x for some 'excess' value x. Let's code up those possibilities.

```
data =Bounded?_ (u : Nat) : Nat \rightarrow Set where

yes : (i : Fin \ u) \rightarrow u - Bounded? (fog \ i)

no : (x : Nat) \rightarrow u - Bounded? (u + N x)
```

If we had a value in u –Bounded? n, inspecting it would tell us which of those two possibilities applies. Let us show that we can always construct such a value. The base cases are straight forward, but something rather unusual happens in the step.

If we are to compare $\operatorname{suc} u$ with $\operatorname{suc} n$, we surely need to know the result of comparing u with n. The with construct McBride and McKinna [2004] allows us to grab the result of that comparison and add a column for it to our pattern match. You can see that the subsequent lines tabulate the possible outcomes of the match, as well as showing patterns for the original arguments. Moreover, something funny happens to those patterns: n becomes instantiated with the non-constructor expressions corresponding to the in- and out-of-bounds cases, marked with a dot. Operationally, there is no need to check that n takes the form indicated by the dotted pattern: the operational check is a constructor case analysis on the result of the

recursive call, and the consequent analysis of n is forced by the types of those constructors. We work hard to make values in precise types, and we get repaid with information when we inspect those values!

The possibility that that inspecting one value might induce knowledge of another is a phenomenon new with dependent types, and it necessitates some thought about our programming notation, and also our selection of what programs to write. When we write functions to inspect data, we should ask what the types of those functions tell us about what the inspection will learn.

Finite Set Structure 3.0.7

The natural numbers can be thought of as names for finite types. We can equip these finite types with lots of useful structure.

Let's start with the *coproduct* structure, corresponding to addition. We can see Fin $(m +_{N} n)$ as the disjoint union of Fin m (at the left, low end of the range) and Fin n (at the right, high end of the range). Let us implement the injections. Firstly, finl embeds Fin m, preserving numerical value. I am careful to make the value of m visible, as you can't easily guess it from $m +_{N} n$.

```
finl : (m : \mathsf{Nat}) \{ n : \mathsf{Nat} \} \to \mathsf{Fin} \ m \to \mathsf{Fin} \ (m +_{\mathsf{N}} n)
finl zero ()
finl (suc m) zero = zero
finl (suc m) (suc i) = suc (finl m i)
```

Secondly, finr embeds Fin n by shifting its values up by m.

```
finr : (m : \mathsf{Nat}) \{ n : \mathsf{Nat} \} \to \mathsf{Fin} \ n \to \mathsf{Fin} \ (m +_{\mathsf{N}} n)
finr zero i = i
finr (suc m) i = suc (finr m i)
```

Landin: if a job's worth half-doing.

Injections leave the job half done We need to be able to tell them apart. We can worth doing, it's certainly split $Fin(m +_N n)$ as a disjoint union.

```
\mathsf{inl}\,:\,S\to S+\,T
  inr: T \rightarrow S + T
\mathsf{finIr} \,:\, (m \,:\, \mathsf{Nat}) \,\, \{\, n \,:\, \mathsf{Nat} \,\} \,\,{\to}\,\, \mathsf{Fin} \,\, (m \,\,+_{\mathsf{N}} \,\,n) \,\,{\to}\,\, \mathsf{Fin} \,\, m \,+\, \mathsf{Fin} \,\, n
                        = inr k
finlr zero k
finlr (suc m) zero
                                         = inl zero
finlr (suc m) (suc k) with finlr m k
                            | inl i = inl (suc i)
                                  inr j = inr j
```

However, that still leaves work undone. Here's another function of the same type.

```
\mathsf{badIr} \,:\, (m \,:\, \mathsf{Nat}) \,\{\, n \,:\, \mathsf{Nat} \,\} \to \mathsf{Fin} \,(m \,+_{\mathsf{N}} \,n) \to \mathsf{Fin} \,m + \mathsf{Fin} \,n
badlr zero { zero } ()
badlr zero \{ suc \ n \} = inr zero
badlr (suc m) _ = inl zero
```

As you can see, it ignores its argument, except where necessary to reject the input, and it returns the answer that's as far to the left as possible under the circumstances.

The type of our testing function finlr makes no promise as to what the test will tell us about the value being tested. We compute a value in a disjoint union, but we *learn* nothing about the values we already possess. There's still time to change all that. We can show that the finl and finr injections *cover* Fin $(m +_N n)$ by constructing a *view*. Firstly, let us state what it means to be in the image of finl or finr.

```
data FinSum (m \ n : \mathsf{Nat}) : \mathsf{Fin} \ (m +_{\mathsf{N}} \ n) \to \mathsf{Set} where isFinI : (i : \mathsf{Fin} \ m) \to \mathsf{FinSum} \ m \ n \ (\mathsf{finI} \ m \ i) isFinr : (j : \mathsf{Fin} \ n) \to \mathsf{FinSum} \ m \ n \ (\mathsf{finr} \ m \ j)
```

Then let us show that every element is in one image or the other.

```
\begin{array}{lll} \operatorname{finSum} : (m:\operatorname{Nat}) \ \{n:\operatorname{Nat}\} \ (k:\operatorname{Fin} \ (m+_{\operatorname{N}} \ n)) \to \operatorname{FinSum} \ m \ n \ k \\ \operatorname{finSum} \operatorname{zero} & = \operatorname{isFinr} \ k \\ \operatorname{finSum} \ (\operatorname{suc} \ m) \ \operatorname{zero} & = \operatorname{isFinl} \operatorname{zero} \\ \operatorname{finSum} \ (\operatorname{suc} \ m) \ (\operatorname{suc} \ k) & \text{with} \ \operatorname{finSum} \ m \ k \\ \operatorname{finSum} \ (\operatorname{suc} \ m) \ (\operatorname{suc} \ .(\operatorname{finl} \ m \ i)) \ | \ \operatorname{isFinl} \ i \ = \operatorname{isFinl} \ (\operatorname{suc} \ i) \\ \operatorname{finSum} \ (\operatorname{suc} \ m) \ (\operatorname{suc} \ .(\operatorname{finr} \ m \ j)) \ | \ \operatorname{isFinr} \ j \ = \operatorname{isFinr} \ j \end{array}
```

Note that the case analysis on the result of finSum m k exposes which injection made k, directly in the patterns.

3.0.8 Finish the Job

Exercise 3.1 (Products) *Equip* Fin with its product structure. Implement the constructor

```
fpair : (m \ n : \mathsf{Nat}) \to \mathsf{Fin} \ m \to \mathsf{Fin} \ n \to \mathsf{Fin} \ (m \times_{\mathsf{N}} n)
```

then show that it covers by constructing the appropriate view. Use your view to implement the projections.

Exercise 3.2 (Exponentials) *Implement the exponential function for* Nat.

```
^{N}_{-}: Nat \rightarrow Nat \rightarrow Nat
```

Now implement the abstraction operator which codifies the finitely many functions between Fin m and Fin n. (You know how to tabulate a function; you know that a vector, like an exponential, is an iterated product.)

```
\mathsf{flam} \ : \ (m \ n \ : \ \mathsf{Nat}) \to (\mathsf{Fin} \ m \to \mathsf{Fin} \ n) \to \mathsf{Fin} \ (n^{\mathsf{-N}} \ m)
```

Show that flam covers, and thus implement application. You will not be able to show that every function is given by applying a code, for that is true only up to an extensional equality which is not realised in Agda.

Exercise 3.3 (Masochism) Implement dependent functions and pairs!

3.0.9 One Song to the Tune of Another (with James McKinna)

Let's define positive binary numbers as snoc-lists of bits.

```
Bin = Context 22
```

We can define a 'one' and a 'successor' operation for these numbers.

```
bone : Bin bone = \langle \rangle
```

```
\begin{array}{ll} \mathsf{bsuc} \,:\, \mathsf{Bin} \to \mathsf{Bin} \\ \mathsf{bsuc} \,\, \langle \rangle &=\, \langle \rangle, \mathsf{ff} \\ \mathsf{bsuc} \,\, (b,\mathsf{ff}) &=\, b, \mathsf{tt} \\ \mathsf{bsuc} \,\, (b,\mathsf{tt}) &=\, \mathsf{bsuc} \,\, b, \mathsf{ff} \end{array}
```

It's fun to write binary arithmetic operations, but our mission just now is to establish that we can still *reason* about these numbers as we did with unary numbers. To do so, we must establish Peano's induction principle for binary numbers. That is, we need to implement the following:

```
\begin{array}{c} \mathsf{peanoBin} \,:\, (P\,:\, \mathsf{Bin} \to \mathsf{Set}) \to \\ & (P\,\,\mathsf{bone}) \to \\ & ((b\,:\, \mathsf{Bin}) \to P\,\,b \to P\,\,(\mathsf{bsuc}\,\,b)) \to \\ & (b\,:\, \mathsf{Bin}) \to P\,\,b \\ \\ \mathsf{peanoBin}\,\,P\,\,pone\,\,psuc\,\,=\,\,\mathsf{help}\,\,\mathbf{where} \\ & \mathsf{help}\,:\, (b\,:\, \mathsf{Bin}) \to P\,\,b \\ & \mathsf{help}\,\,b\,\,=\,? \end{array}
```

This goes horribly wrong. How to fix?

Chapter 4

Generic Programming

A *universe* is a collection of types, given as the image of a function. A simple example is the universe

```
data Zero : Set where -- no constructors! TT : 2 \rightarrow Set TT tt = 11 TT ff = Zero
```

TT gives you a universe of sets corresponding to *decidable* propositions. You can use TT to attach decidable preconditions to functions. The standard example is this

```
\begin{array}{lll} \text{le} : \operatorname{Nat} \to \operatorname{Nat} \to \mathbf{2} \\ \text{le zero} & n & = & \operatorname{tt} \\ \text{le } (\operatorname{suc} m) \operatorname{zero} & = & \operatorname{ff} \\ \text{le } (\operatorname{suc} m) (\operatorname{suc} n) & = & \operatorname{le} m \ n \\ & -_{\operatorname{N-}} : (m \ n : \operatorname{Nat}) \left\{ p : \operatorname{TT} \left( \operatorname{le} n \ m \right) \right\} \to \operatorname{Nat} \\ (m & -_{\operatorname{N}} \operatorname{zero}) & = & m \\ (\operatorname{zero} & -_{\operatorname{N}} \operatorname{suc} _{-}) \left\{ () \right\} \\ (\operatorname{suc} m -_{\operatorname{N}} \operatorname{suc} n) \left\{ p \right\} & = & (m -_{\operatorname{N}} n) \left\{ p \right\} \\ \operatorname{exampleSubtraction} & : & \operatorname{Nat} \\ \operatorname{exampleSubtraction} & : & \operatorname{Nat} \\ \operatorname{exampleNonSubtraction} & : & \operatorname{Nat} \\ \operatorname{exampleNonSubtraction} & : & \operatorname{Nat} \\ \operatorname{exampleNonSubtraction} & = & 37 -_{\operatorname{N}} 42 \end{array}
```
